

# **Marry for What? Caste and Mate Selection in Modern India**

By Abhijit Banerjee, Esther Duflo, Maitreesh Ghatak and Jeanne Lafortune

## **DATA FILES**

The zip file contains 6 subfolders which must be extracted jointly to a given location. For any Stata execution, the directory must be set as the one including all 6 subfolders. The data generated by the do-file will be saved in the “data” folder, the log file under the “log” folder and the output tables in the “tab” folder. On the other hand, Matlab programs must be run within the “matlab” folder and R programs must be run within the “R” folder.

The folder data includes 8 data files (codes used are included in the file code.pdf):

- ads\_ads\_AEJ matches interviewed adplacers (identified by the id number si) who replied to ads in the newspaper to all ads published on that particular Sunday and identifies the one they replied to. If any of these ads were from our sample, they are identified with the SI id number.
- ads\_AEJ provides information about the ad content of each ad in our interview sample (identified by the id number SI)
- allads\_AEJ contains the ad content of all ads in the Sunday editions of the newspaper.
- interview\_AEJ contains the answers of the adplacers (identified by the id number SI) to the two rounds of interviews
- letters\_AEJ contains the information included in the letters sent to the adplacers (identified by the id number SI)
- match\_AEJ contains information, collected during the second round of interviews, regarding the match of adplacers (identified by the id number SI)
- reverse\_bridewanted\_AEJ matches a letter writer (by a prospective bride) to all ads that were published on the Sunday edition where she replied to one of our interview adplacers.
- reverse\_groomwanted\_AEJ matches a letter writer (by a prospective groom) to all ads that were published on the Sunday edition where he replied to one of our interview adplacers.

To replicate Tables 1-5, Figure 2 and Online Appendix Tables C1-C2, C4-C10, one needs to run the Stata do-file Data\_Analysis by typing do “do/Data\_Analysis”.

To replicate Figure 1, one needs to run the programs “bridewanted.R” and “groomwanted.R” using the statistical package R while being inside the “R” subfolder. This will generate an output “beta\_bridewanted\_withZ.csv” and “beta\_groomwanted\_withZ.csv”. From the bridewanted

file, one must extract the 18<sup>th</sup> parameter while in the groomwanted file, the 13<sup>th</sup> one. They must then be plotted to obtain Figure 1.

To obtain the bootstrapped parameter values that enter into the simulations, one must run the do-file “bootstrap\_witherrors” in Stata.

To replicate Table 6 and 8 as well as Online Appendix Table C12, one must run in Matlab the m-file “algorithm\_new” (Will take about 2 weeks on an average computer). One must then run in Stata, the do-file “do/correlations\_results” and “do/correlations\_results\_cons” to obtain the simulated results and the do-file “do/correlations\_stable” to obtain the observed statistics (entries for the table will be found inside the log files).

To replicate Table 7, one must run in Matlab the m-files “algorithm\_nocaste\_new” and “algorithm\_withincaste\_new”. Then, one must run in Stata the do-files “do/correlations\_results\_caste” and “do/correlations\_results\_nocaste” (entries for the table will be found inside the log files).

To replicate Online Appendix Table C13, one must run in Matlab the m-files “algorithm\_rev\_new” and “algorithm\_balanced\_new”. Then, one must run in Stata the do-files “do/correlations\_results\_reverse” and “do/correlations\_results\_balanced” (entries for the table will be found inside the log files).

To replicate Online Appendix Table C14, one must first run in Matlab the m-files “algorithm\_hetero” and “algorithm\_withnoise”. Then, one must run in Stata the do-files “do/correlations\_results\_hetero” and “do/correlations\_results\_withnoise” (entries for the table will be found inside the log files).
